

# Using uM-FPU V2 with the BASIC Stamp<sup>®</sup>

*Micromega Corporation*

## Introduction

The uM-FPU is a 32-bit floating point coprocessor that can be easily interfaced with the BASIC Stamp<sup>®</sup> BS2, BS2e, BS2sx, BS2p24, BS2p40, BS2pe, or BS2px to provide support for 32-bit IEEE 754 floating point operations and 32-bit long integer operations. The uM-FPU supports both I<sup>2</sup>C and 2-Wire SPI connections.

## uM-FPU V2 Features

- 8-pin integrated circuit.
- I<sup>2</sup>C compatible interface up to 400 kHz
- SPI compatible interface up to 4 Mhz
- 32 byte instruction buffer
- Sixteen 32-bit general purpose registers for storing floating point or long integer values
- Five 32-bit temporary registers with support for nested calculations (i.e. parentheses)
- Floating Point Operations
  - Set, Add, Subtract, Multiply, Divide
  - Sqrt, Log, Log10, Exp, Exp10, Power, Root
  - Sin, Cos, Tan, Asin, Acos, Atan, Atan2
  - Floor, Ceil, Round, Min, Max, Fraction
  - Negate, Abs, Inverse
  - Convert Radians to Degrees, Convert Degrees to Radians
  - Read, Compare, Status
- Long Integer Operations
  - Set, Add, Subtract, Multiply, Divide, Unsigned Divide
  - Increment, Decrement, Negate, Abs
  - And, Or, Xor, Not, Shift
  - Read 8-bit, 16-bit, and 32-bit
  - Compare, Unsigned Compare, Status
- Conversion Functions
  - Convert 8-bit and 16-bit integers to floating point
  - Convert 8-bit and 16-bit integers to long integer
  - Convert long integer to floating point
  - Convert floating point to long integer
  - Convert floating point to formatted ASCII
  - Convert long integer to formatted ASCII
  - Convert ASCII to floating point
  - Convert ASCII to long integer
- User Defined Functions can be stored in Flash memory
  - Conditional execution
  - Table lookup
  - N<sup>th</sup> order polynomials

## Pin Diagram and Pin Description

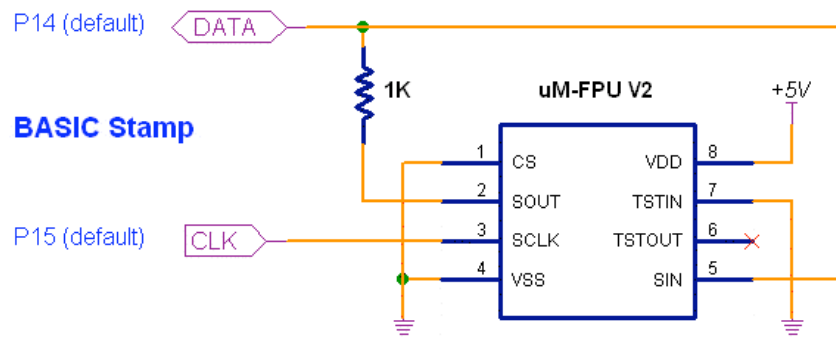

Pin	Name	Type	Description
1	CS	Input	Chip Select
2	SOUT	Output	SPI Output Busy/Ready
3	SCLK SCL	Input	SPI Clock I <sup>2</sup> C Clock
4	VSS	Power	Ground
5	SIN SDA	Input In/Out	SPI Input I <sup>2</sup> C Data
6	TSTOUT	Output	Test Output
7	TSTIN	Input	Test Input
8	VDD	Power	Supply Voltage

## Connecting uM-FPU V2 to the BASIC Stamp using 2-wire SPI

The uM-FPU requires just two pins for interfacing to the BASIC Stamp. The communication is implemented using a bidirectional serial interface that requires a clock pin and a data pin. The default setting for these pins are:

FpuClk	Pin 15
FpuOut	Pin 14
FpuIn	Pin 14

The settings for these pins can be changed to suit your application. By default, the uM-FPU chip is always selected, so the FpuClk and FpuIn/FpuOut pins should not be used for other connections as this will likely result in loss of synchronization between the BASIC Stamp and the uM-FPU coprocessor.

## Connecting uM-FPU V2 to the BASIC Stamp using I<sup>2</sup>C

The uM-FPU V2 can also be connected using an I<sup>2</sup>C interface. The default slaveID for the uM-FPU is \$C8. The default settings for the I<sup>2</sup>C pins is:

FpuPin          Pin 0    (SDA is Pin 0, SCL is Pin 1)

The settings for these pins can be changed to suit your application.

## An Introduction to the uM-FPU

The following section provides an introduction to the uM-FPU using BASIC Stamp commands for all of the examples. For more detailed information about the uM-FPU, please refer to the following documents:

<i>uM-FPU V2 Datasheet</i>	functional description and hardware specifications
<i>uM-FPU V2 Instruction Set</i>	full description of each instruction

## uM-FPU Registers

The uM-FPU contains sixteen 32-bit registers, numbered 0 through 15, which are used to store floating point or long integer values. Register 0 is reserved for use as a temporary register and is modified by some of the uM-FPU operations. Registers 1 through 15 are available for general use. Arithmetic operations are defined in terms of an A register and a B register. Any of the 16 registers can be selected as the A or B register.

**uM-FPU Registers**

	0	32-bit Register
	1	32-bit Register
<b>A</b> →	2	32-bit Register
	3	32-bit Register
	4	32-bit Register
<b>B</b> →	5	32-bit Register
	6	32-bit Register
	7	32-bit Register
	8	32-bit Register
	9	32-bit Register
	10	32-bit Register
	11	32-bit Register
	12	32-bit Register
	13	32-bit Register
	14	32-bit Register
	15	32-bit Register

The **FADD** instruction adds two floating point values and is defined as  $A = A + B$ . To add the value in register 5 to the value in register 2, you would do the following:

- Select register 2 as the A register
- Select register 5 as the B register
- Send the **FADD** instruction ( $A = A + B$ )

We'll look at how to send these instructions to the uM-FPU in the next section.

Register 0 is a temporary register. If you want to use a value later in your program, store it in one of the registers 1 to 15. Several instructions load register 0 with a temporary value, and then select register 0 as the B register. As you will see shortly, this is very convenient because other instructions can use the value in register 0 immediately.

## Sending Instructions to the uM-FPU

Appendix A contains a table that gives a summary of each uM-FPU instruction, with enough information to follow the examples in this document. For a detailed description of each instruction, refer to the document entitled *uM-FPU Instruction Set*.

To send instructions to the uM-FPU using an SPI interface, the **SHIFTOUT** command is used as follows:

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [FADD+5]
```

To send instructions to the uM-FPU using an I<sup>2</sup>C interface, the **I2COUT** command is used as follows:

```
I2COUT FpuOut, FpuClk, MSBFIRST, [FADD+5]
```

The part inside the square brackets specifies the instructions and data to send to the uM-FPU. The part before the square brackets is always the same, and depends on whether you are using an SPI or I<sup>2</sup>C interface. It tells the BASIC Stamp how to communicate with the uM-FPU. The SHIFTOUT command will be used for the examples in this document, but everything applies equally well to the I2COUT command. Note: There is one difference when sending a Word variable. The SHIFTOUT command can use the [dataWord\16] syntax, whereas I2COUT only sends 8 bit bytes, so the syntax would be [dataWord.HIGHBYTE, dataWord.LOWBYTE].

All instructions start with an opcode that tells the uM-FPU which operation to perform. Some instructions require additional data or arguments, and some instructions return data. The most common instructions (the ones shown in the first half of the table in Appendix A), require a single byte for the opcode. For example:

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [SQRT]
```

The instructions in the last half of the table, are extended opcodes, and require a two byte opcode. The first byte of extended opcodes is always \$FE, defined as XOP. To use an extended opcode, you send the XOP byte first, followed by the extended opcode. For example:

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, ATAN]
```

Some of the most commonly used instructions use the lower 4 bits of the opcode to select a register. This allows them to select a register and perform an operation at the same time. Opcodes that include a register value are defined with the register value equal to 0, so using the opcode by itself selects register 0. The following command selects register 0 as the B register then calculates  $A = A + B$ .

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [FADD]
```

To select a different register, you simply add the register value to the opcode. The following command selects register 5 as the B register then calculates  $A = A + B$ .

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [FADD+5]
```

Let's look at a more complete example. Earlier, we described the steps required to add the value in register 5 to the value in register 2. The command to perform that operation is as follows:

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [SELECTA+2, FADD+5]
```

*Description:*

SELECTA+2	select register 2 as the A register
FADD+5	select register 5 as the B register and calculate $A = A + B$

It's a good idea to use constant definitions to provide meaningful names for the registers. This makes your program code easier to read and understand. The same example using constant definitions would be:

```
Total CON 2          'total amount (uM-FPU register)
Count  CON 5          'current count (uM-FPU register)
```

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [SELECTA+Total, FADD+Count]
```

Selecting the A register is such a common occurrence, it was defined as opcode \$0x. The definition for SELECTA is \$00, so SELECTA+Total is the same as just using Total by itself. Using this shortcut, the same example would now be:

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Total, FADD+Count]
```

## Tutorial Examples

Now that we've introduced some of the basic concepts of sending instructions to the uM-FPU, let's go through a tutorial example to get a better understanding of how it all ties together. This example will take a temperature reading from a DS1620 digital thermometer and convert it to Celsius and Fahrenheit.

Most of the data read from devices connected to the BASIC Stamp will return some type of integer value. In this example, the interface routine for the DS1620 reads a 9-bit value and stores it in a Word variable on the BASIC Stamp called rawTemp. The value returned by the DS1620 is the temperature in units of 1/2 degrees Celsius. We need to load this value to the uM-FPU and convert it to floating point. The following command is used:

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [DegC, LOADWORD, rawTemp\16, FSET]
```

*Description:*

DegC	select DegC as the A register
LOADWORD, rawTemp\16	load rawTemp to register 0, convert to floating point, select register 0 as the B register
FSET	DegC = register 0 (i.e. the floating point value of rawTemp)

The uM-FPU register DegC now contains the value read from the DS1620 (converted to floating point). Since the DS1620 works in units of 1/2 degree Celsius, DegC will be divided by 2 to get the degrees in Celsius.

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [LOADBYTE, 2, FDIV]
```

*Description:*

LOADBYTE, 2	load the value 2 to register 0, convert to floating point, select register 0 as the B register
FDIV	divide DegC by register 0 (i.e. divide by 2)

To get the degrees in Fahrenheit we will use the formula  $F = C * 1.8 + 32$ . Since 1.8 and 32 are constant values, they would normally be loaded once in the initialization section of your program and used later in the main program. The value 1.8 is loaded by using the ATOF (ASCII to float) instruction as follows:

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [F1_8, ATOF, "1.8", 0, FSET]
```

*Description:*

F1.8	select F1_8 as the A register
ATOF, "1.8", 0	load the string 1.8 (note: the string must be zero terminated)
FSET	convert the string to floating point, store in register 0, select register 0 as the B register
	set F1_8 to the value in register 0 (i.e. 1.8)

The value 32 is loaded using the LOADBYTE instruction as follows:

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [F32, LOADBYTE, 32, FSET]
```

*Description:*

F32	select F32 as the A register
LOADBYTE, 32	load the value 32 to register 0, convert to floating point, select register 0 as the B register
FSET	set F32 to the value in register 0 (i.e. 32.0)

Now using these constant values we calculate the degrees in Fahrenheit as follows:

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [DegF, FSET+DegC, FMUL+F0_9, FADD+F32]
```

*Description:*

DegF	select DegF as the A register
FSET+DegC	set DegF = DegC
FMUL+F1_8	multiply DegF by 1.8
FADD+F32	add 32.0 to DegF

Now we print the results. There are support routines provided for printing floating point numbers. `Print_Float` prints an unformatted floating point value and displays up to eight digits of precision. `Print_FloatFormat` prints a formatted floating point number. We'll use `Print_FloatFormat` to display the results. The `format` variable is used to select the desired format. The tens digit is the total number of characters to display, and the ones digit is the number of digits after the decimal point. The DS1620 has a maximum temperature of 125° Celsius and one decimal point of precision, so we'll use a format of 51. Before calling the print routine the uM-FPU register is selected and the `format` variable is set. The following example prints the temperature in degrees Fahrenheit.

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [DegF]
format = 51
GOSUB Print_FloatFormat
```

Sample code for this tutorial and a wiring diagram for the DS1620 are shown at the end of this document. The file *demo1.bs2* is also included with the support software. There is a second file called *demo2.bs2* that extends this demo to include minimum and maximum temperature calculations. If you have a DS1620 you can wire up the circuit and try out the demos.

## uM-FPU Support Software for the BASIC Stamp

Two template files contain all of the definitions and support code required for communicating with the uM-FPU.

<code>umfpu-spi.bs2</code>	provides support for a 2-wire SPI connection
<code>umfpu-i2c.bsp</code>	provides support for an I <sup>2</sup> C connection.

These files can be used directly as the starting point for a new program, or the definitions and support code can be copied from this file to another program. They contain the following:

- pin definitions for the uM-FPU
- opcode definitions for all uM-FPU instructions
- various definitions for the `Word` variable used by the support routines
- a sample program with a place to insert your application code
- the support routines described below

### Fpu\_Reset

To ensure that the BASIC Stamp and the uM-FPU coprocessor are synchronized, a reset call must be done at the start of every program. The `Fpu_Reset` routine resets the uM-FPU, confirms communications, and sets the status variable to 1 if successful, or 0 if the reset failed. A sample reset call is included in the *umfpu-spi.bs2* and *umfpu-i2c.bsp* files.

### Fpu\_Wait

The uM-FPU must have completed all calculations and be ready to return the data before sending an instruction that reads data from the uM-FPU. The `Fpu_Wait` routine checks the status of the uM-FPU and waits until it is ready. The print routines check the ready status, so it isn't necessary to call `Fpu_Wait` before calling a print routine. If your program reads directly from the uM-FPU using the `SHIFTIN` or `I2CIN` commands, a call to `Fpu_Wait` must be made prior to sending the read instruction. An example of reading a byte value is as follows:

```
GOSUB Fpu_wait
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, READBYTE]
SHIFTIN FpuOut, FpuClk, MSBPRES, [dataByte]
```

#### Description:

- wait for the uM-FPU to be ready
- send the `READBYTE` instruction
- read a byte value and store it in the variable `dataByte`

The uM-FPU V2 has a 32 byte instruction buffer. In most cases, data will be read back before 32 bytes have been sent to the uM-FPU. If a long calculation is done that requires more than 32 bytes to be sent to the uM-FPU, an `Fpu_Wait` call should be made at least every 32 bytes to ensure that the instruction buffer doesn't overflow.

**Print\_Version**

Prints the uM-FPU version string to the PC screen using the DEBUG command.

**Print\_Float**

The value in register A is displayed on the PC screen as a floating point value using the DEBUG command. Up to eight significant digits will be displayed if required. Very large or very small numbers are displayed in exponential notation. The length of the displayed value is variable and can be from 3 to 12 characters in length. The special cases of NaN (Not a Number), +Infinity, -Infinity, and -0.0 are handled. Examples of the display format are as follows:

1.0	NaN	0.0
1.5e20	Infinity	-0.0
3.1415927	-Infinity	1.0
-52.333334	-3.5e-5	0.01

**Print\_FloatFormat**

The value in register A is displayed on the PC screen as a formatted floating point value using the DEBUG command. The `format` variable is used to specify the desired format. The tens digit specifies the total number of characters to display and the ones digit specifies the number of digits after the decimal point. If the value is too large for the format specified, then asterisks will be displayed. If the number of digits after the decimal points is zero, no decimal point will be displayed. Examples of the display format are as follows:

Value in A register	format	Display format
123.567	61 (6.1)	123.6
123.567	62 (6.2)	123.57
123.567	42 (4.2)	*.*
0.9999	20 (2.0)	1
0.9999	31 (3.1)	1.0

**Print\_Long**

The value in register A is displayed on the PC screen as a signed long integer using the DEBUG command. The displayed value can range from 1 to 11 characters in length. Examples of the display format are as follows:

```
1
500000
-3598390
```

**Print\_LongFormat**

The value in register A is displayed on the PC screen as a formatted long integer using the DEBUG command. The `format` variable is used to specify the desired format. A value between 0 and 15 specifies the width of the display field for a signed long integer. The number is displayed right justified. If 100 is added to the format value the value is displayed as an unsigned long integer. If the value is larger than the specified width, asterisks will be displayed. If the width is specified as zero, the length will be variable. Examples of the display format are as follows:

Value in register A	format	Display format
-1	10 (signed 10)	-1
-1	110 (unsigned 10)	4294967295
-1	4 (signed 4)	-1
-1	104 (unsigned 4)	****
0	4 (signed 4)	0
0	0 (unformatted)	0
1000	6 (signed 6)	1000

**Loading Data Values to the uM-FPU**

There are several instructions for loading integer values to the uM-FPU. These instructions take an integer value as an argument, stores the value in register 0, converts it to floating point, and selects register 0 as the B register. This allows the loaded value to be used immediately by the next instruction.

LOADBYTE	Load 8-bit signed integer and convert to floating point
LOADUBYTE	Load 8-bit unsigned integer and convert to floating point

LOADWORD	Load 16-bit signed integer and convert to floating point
LOADUWORD	Load 16-bit unsigned integer and convert to floating point

For example, to calculate  $\text{Result} = \text{Result} + 20.0$

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Result, LOADBYTE, 20, FADD]
```

*Description:*

Result	select Result as the A register
LOADBYTE, 20	load the value 20 to register 0, convert to floating point, select register 0 as the B register
FADD	add register 0 to Result

The following instructions take integer value as an argument, stores the value in register 0, converts it to a long integer, and selects register 0 as the B register.

LONGBYTE	Load 8-bit signed integer and convert to 32-bit long signed integer
LONGUBYTE	Load 8-bit unsigned integer and convert to 32-bit long unsigned integer
LONGWORD	Load 16-bit signed integer and convert to 32-bit long signed integer
LONGUWORD	Load 16-bit unsigned integer and convert to 32-bit long unsigned integer

For example, to calculate  $\text{Total} = \text{Total} / 100$

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Total, XOP, LONGBYTE, 100, LDIV]
```

*Description:*

Total	select Total as the A register
XOP, LONGBYTE, 100	load the value 100 to register 0, convert to long integer, select register 0 as the B register
LDIV	divide Total by register 0

There are several instructions for loading commonly used constants. These instructions load the constant value to register 0, and select register 0 as the B register.

LOADZERO	Load the floating point value 0.0 (or long integer 0)
LOADONE	Load the floating point value 1.0
LOADE	Load the floating point value of e (2.7182818)
LOADPI	Load the floating point value of pi (3.1415927)

For example, to set  $\text{Result} = 0.0$

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Result, XOP, LOADZERO, FSET]
```

*Description:*

Result	select Result as the A register
XOP, LOADZERO	load 0.0 the register 0 and selects register 0 as the B register
FSET	set Result to the value in register 0 (Result = 0.0)

There are two instructions for loading 32-bit floating point values to a specified register. This is one of the more efficient ways to load floating point constants, but requires knowledge of the internal representation for floating point numbers (see Appendix B). A handy utility program called *uM-FPU Converter* is available to convert between floating point strings and 32-bit hexadecimal values.

FWRITEA	Write 32-bit floating point value to specified register
FWRITAB	Write 32-bit floating point value to specified register

For example, to set  $\text{Angle} = 20.0$  (the floating point representation for 20.0 is \$41A00000)

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [FWRITEA+Angle, $41,$A0,$00,$00]
```

*Description:*

FWRITEA+Angle	select Angle as the A register and load 32-bit value
\$41,\$A0,\$00,\$00	the value \$41A00000 is loaded to Angle

There are two instructions for loading 32-bit long integer values to a specified register.

LWRITEA	Write 32-bit long integer value to specified register
LWRITAB	Write 32-bit long integer value to specified register

For example, to set Total = 500000

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, LWRITEA+Total, $00,$07,$A1,$20]
```

*Description:*

XOP, LWRITEA+Total	select Total as the A register and load 32-bit value
\$00,\$07,\$A1,\$20	the value \$0007A120 is loaded to Total

There are two instructions for converting strings to floating point or long integer values.

ATOF	Load ASCII string and convert to floating point
ATOL	Load ASCII string and convert to long integer

For example, to set Angle = 1.5885

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Angle, ATOF, "1.5885", 0, FSET]
```

*Description:*

Angle	select Angle as the A register
ATOF, "1.5885", 0	load the string 1.5885 to the uM-FPU and convert to floating point (note the string must be zero terminated) the value is stored in register 0 and register 0 is selected as the B register
FSET	set Angle to the value in register 0

For example, to set Total = 500000

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Total, ATOL, "5000000", 0, FSET]
```

*Description:*

Total	select Total as the A register
ATOL, "5000000", 0	load the string 500000 to the uM-FPU and convert to floating point (note the string must be zero terminated) the value is stored in register 0 and register 0 is selected as the B register
LSET	set Total to the value in register 0

The fastest operations occur when the uM-FPU registers are already loaded with values. In time critical portions of code floating point constants should be loaded beforehand to maximize the processing speed in the critical section. With 15 registers available for storage on the uM-FPU, it is often possible to preload all of the required constants. In non-critical sections of code, data and constants can be loaded as required.

## Reading Data Values from the uM-FPU

There are two instruction for reading 32-bit floating point values from the uM-FPU.

READFLOAT	Reads a 32-bit floating point value from the A register.
FREAD	Reads a 32-bit floating point value from the specified register.

The following commands read the floating point value from the A register

```
GOSUB Fpu_wait
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, READFLOAT]
SHIFTIN FpuOut, FpuClk, MSBPRES, [byte0, byte1, byte2, byte3]
```

*Description:*

- wait for the uM-FPU to be ready

- send the READFLOAT instruction
- read the 32-bit value and store it in variables `byte0`, `byte1`, `byte2`, `byte3`

There are four instruction for reading integer values from the uM-FPU.

<code>READBYTE</code>	Reads the lower 8 bits of the value in the A register.
<code>READWORD</code>	Reads the lower 16 bits of the value in the A register.
<code>READLONG</code>	Reads a 32-bit long integer value from the A register.
<code>LREAD</code>	Reads a 32-bit long integer value from the specified register.

The following commands read the lower 8 bits from the A register

```
GOSUB Fpu_wait
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, READBYTE]
SHIFTIN FpuOut, FpuClk, MSBPRES, [dataByte]
```

*Description:*

- wait for the uM-FPU to be ready
- send the READBYTE instruction
- read a byte value and store it in the variable `dataByte`

## Comparing and Testing Floating Point Values

A floating point value can be zero, positive, negative, infinite, or Not a Number (which occurs if an invalid operation is performed on a floating point value). To check the status of a floating point number the `FSTATUS` instruction is sent, and the returned byte is stored in the `status` variable. A bit definition is provided for each status bit in the `status` variable. They are as follows:

<code>status_Zero</code>	Zero status bit (0-not zero, 1-zero)
<code>status_Sign</code>	Sign status bit (0-positive, 1-negative)
<code>status_NaN</code>	Not a Number status bit (0-valid number, 1-NaN)
<code>status_Inf</code>	Infinity status bit (0-not infinite, 1-infinite)

For example:

```
GOSUB Fpu_wait
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [FSTATUS]
SHIFTIN FpuOut, FpuClk, MSBPRES, [status]
IF (status_Sign = 1) THEN DEBUG "Result is negative"
IF (status_Zero = 1) THEN DEBUG "Result is zero"
```

The `FCOMPARE` instruction is used to compare two floating point values. The status bits are set for the results of the operation  $A - B$  (The selected A and B registers are not modified). For example, the following commands compare the values in registers `Value1` and `Value2`.

```
GOSUB Fpu_wait
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Value1, SELECTB+Value2, FCOMPARE]
SHIFTIN FpuOut, FpuClk, MSBPRES, [status]

IF (status_Zero = 1) THEN
  DEBUG "Value1 = Value2"
ELSEIF (status_Sign = 1) THEN
  DEBUG "Value1 < Value2"
ELSE
  DEBUG "Value1 > Value2"
ENDIF
```

## Comparing and Testing Long Integer Values

A long integer value can be zero, positive, or negative. To check the status of a long integer number the `LSTATUS` instruction is sent, and the returned byte is stored in the `status` variable. A bit definition is provided for each status bit in the `status` variable. They are as follows:

<code>status_Zero</code>	Zero status bit (0-not zero, 1-zero)
<code>status_Sign</code>	Sign status bit (0-positive, 1-negative)

For example:

```
GOSUB Fpu_wait
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, LSTATUS]
SHIFTIN FpuOut, FpuClk, MSBPRES, [status]
IF (status_Sign = 1) THEN DEBUG "Result is negative"
IF (status_Zero = 1) THEN DEBUG "Result is zero"
```

The LCOMPARE and LUCOMPARE instructions are used to compare two long integer values. The status bits are set for the results of the operation  $A - B$  (The selected A and B registers are not modified). LCOMPARE does a signed compare and LUCOMPARE does an unsigned compare. For example, the following commands compare the values in registers Value1 and Value2.

```
GOSUB Fpu_wait
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Value1, SELECTB+Value2, XOP, LCOMPARE]
SHIFTIN FpuOut, FpuClk, MSBPRES, [status]
IF (status_Zero = 1) THEN
  DEBUG "Value1 = Value2"
ELSEIF (status_Sign = 1) THEN
  DEBUG "Value1 < Value2"
ELSE
  DEBUG "Value1 > Value2"
```

## Left and Right Parenthesis

Mathematical equations are often expressed with parenthesis to define the order of operations. For example  $Y = (X-1) / (X+1)$ . The LEFT and RIGHT parenthesis instructions provide a convenient means of allocating temporary values and changing the order of operations.

When a LEFT parenthesis instruction is sent, the current selection for the A register is saved and the A register is set to reference a temporary register. Operations can now be performed as normal with the temporary register selected as the A register. When a RIGHT parenthesis instruction is sent, the current value of the A register is copied to register 0, register 0 is selected as the B register, and the previous A register selection is restored. The value in register 0 can be used immediately in subsequent operations. Parenthesis can be nested for up to five levels. In most situations, the user's code does not need to select the A register inside parentheses since it is selected automatically by the LEFT and RIGHT parentheses instructions.

In the following example the equation  $Z = \sqrt{X**2 + Y**2}$  is calculated. Note that the original values of X and Y are retained.

```
Xvalue CON 1          'X value (uM-FPU register 1)
Yvalue CON 2          'Y value (uM-FPU register 2)
Zvalue CON 3          'Z value (uM-FPU register 3)

SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Zvalue, FSET+Xvalue, FMUL+Xvalue]
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, LEFT, FSET+Yvalue, FMUL+Yvalue]
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, RIGHT, FADD, FSQRT]
```

### Description:

<code>Zvalue</code>	select Zvalue as the A register
<code>FSET+Xvalue</code>	$Zvalue = Xvalue$
<code>FMUL+Xvalue</code>	$Zvalue = Zvalue * Xvalue$ (i.e. $X**2$ )
<code>XOP, LEFT</code>	save current A register selection, select temporary register as A register (temp)
<code>FSET+Yvalue</code>	$temp = Yvalue$
<code>FMUL+Yvalue</code>	$temp = temp * Yvalue$ (i.e. $Y**2$ )
<code>XOP, RIGHT</code>	store temp to register 0, select Zvalue as A register (previously saved selection)

FADD                                    add register 0 to Zvalue (i.e.  $X^{**2} + Y^{**2}$ )  
 SQRT                                    take the square root of Zvalue

The following example shows  $Y = 10 / (X + 1)$ :

```
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [Yvalue, LOADBYTE, 10, FSET]
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, LEFT, FSET+Xvalue, XOP, LOADONE, FADD]
SHIFTOUT FpuOut, FpuClk, MSBFIRST, [XOP, RIGHT, FDIV]
```

*Description:*

Yvalue	select Yvalue as the A register
LOADBYTE, 10	load the value 10 to register 0, convert to floating point, select register 0 as the B register
FSET	Yvalue = 10.0
XOP, LEFT	save current A register selection, select temporary register as A register (temp)
FSET+Xvalue	temp = Xvalue
XOP, LOADONE	load 1.0 to register 0 and select register 0 as the B register
FADD	temp = temp + 1 (i.e. X+1)
XOP, RIGHT	store temp to register 0, select Yvalue as A register (previously saved selection)
FDIV	divide Yvalue by the value in register 0

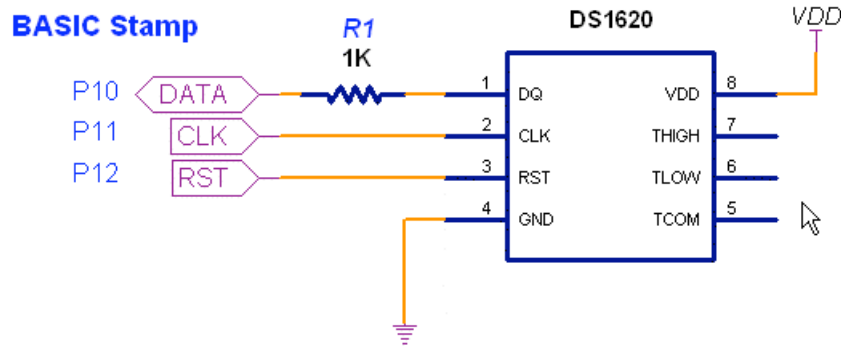

## Further Information

The following documents are also available:

uM-FPU V2 Datasheet	provides hardware details and specifications
uM-FPU V2 Instruction Reference	provides detailed descriptions of each instruction
uM-FPU Application Notes	various application notes and examples

## DS1620 Connections for Demo 1

## Sample Code for Tutorial (Demo1.bs2)

```
'This program demonstrates how to use the uM-FPU floating point coprocessor
'connected to the Basic Stamp over an 2-wire SPI interface. It takes
'temperature readings from a DS1620 digital thermometer, converts them to
'floating point and displays them in degrees Celsius and degrees Fahrenheit.
```

## Appendix A uM-FPU V2 Instruction Summary (BASIC Stamp definitions)

Opcode Name	Data Type	Opcode	Arguments	Returns	B Reg	Description
SELECTA		0x				Select A register
SELECTB		1x			x	Select B register
FWRITEA	Float	2x	yyyy zzzz			Select A register, Write floating point value to A register
FWRITEB	Float	3x	yyyy zzzz		x	Select B register, Write floating point value to B register
FREAD	Float	4x		yyyy zzzz		Read register
FSET/LSET	Either	5x				Select B register, A = B
FADD	Float	6x			x	Select B register, A = A + B
FSUB	Float	7x			x	Select B register, A = A - B
FMUL	Float	8x			x	Select B register, A = A * B
FDIV	Float	9x			x	Select B register, A = A / B
LADD	Long	Ax			x	Select B register, A = A + B
LSUB	Long	Bx			x	Select B register, A = A - B
LMUL	Long	Cx			x	Select B register, A = A * B
LDIV	Long	Dx			x	Select B register, A = A / B Remainder stored in register 0
SQRT	Float	E0				A = sqrt(A)
LOG	Float	E1				A = ln(A)
LOG10	Float	E2				A = log(A)
EXP	Float	E3				A = e ** A
EXP10	Float	E4				A = 10 ** A
SIN (FSIN)	Float	E5				A = sin(A) radians
COS (FCOS)	Float	E6				A = cos(A) radians
TAN (FTAN)	Float	E7				A = tan(A) radians
FLOOR	Float	E8				A = nearest integer <= A
CEIL	Float	E9				A = nearest integer >= A
ROUND	Float	EA				A = nearest integer to A
NEGATE	Float	EB				A = -A
ABS (FABS)	Float	EC				A =  A
INVERSE	Float	ED				A = 1 / A
DEGREES	Float	EE				Convert radians to degrees A = A / (PI / 180)
RADIANS	Float	EF				Convert degrees to radians A = A * (PI / 180)
SYNC		F0		5C		Synchronization
FLOAT	Long	F1			0	Copy A to register 0 Convert long to float
FIX	Float	F2			0	Copy A to register 0 Convert float to long
FCOMPARE	Float	F3		ss		Compare A and B (floating point)
LOADBYTE	Float	F4	bb		0	Write signed byte to register 0 Convert to float
LOADUBYTE	Float	F5	bb		0	Write unsigned byte to register 0 Convert to float
LOADWORD	Float	F6	www		0	Write signed word to register 0 Convert to float
LOADUWORD	Float	F7	www		0	Write unsigned word to register 0 Convert to float

READSTR		F8		aa ... 00		Read zero terminated string from string buffer
ATOF	Float	F9	aa ... 00		0	Convert ASCII to float Store in register 0
FTOA	Float	FA	ff			Convert float to ASCII Store in string buffer
ATOL	Long	FB	aa ... 00		0	Convert ASCII to long Store in register 0
LTOA	Long	FC	ff			Convert long to ASCII Store in string buffer
FSTATUS	Float	FD		ss		Get floating point status of A
XOP		FE				Extended opcode prefix (extended opcodes are listed below)
NOP		FF				No Operation
FUNCTION		FE0n FE1n FE2n FE3n			0	User defined functions 0-15 User defined functions 16-31 User defined functions 32-47 User defined functions 48-63
IF_FSTATUSA	Float	FE80	ss			Execute user function code if FSTATUSA conditions match
IF_FSTATUSB	Float	FE81	ss			Execute user function code if FSTATUSB conditions match
IF_FCOMPARE	Float	FE82	ss			Execute user function code if FCOMPARE conditions match
IF_LSTATUSA	Long	FE83	ss			Execute user function code if LSTATUSA conditions match
IF_LSTATUSB	Long	FE84	ss			Execute user function code if LSTATUSB conditions match
IF_LCOMPARE	Long	FE85	ss			Execute user function code if LCOMPARE conditions match
IF_LUCOMPARE	Long	FE86	ss			Execute user function code if LUCOMPARE conditions match
IF_LTST	Long	FE87	ss			Execute user function code if LTST conditions match
TABLE	Either	FE88				Table Lookup (user function)
POLY	Float	FE89				Calculate n <sup>th</sup> degree polynomial (user function)
READBYTE	Long	FE90		bb		Get lower 8 bits of register A
READWORD	Long	FE91		www		Get lower 16 bits of register A
READLONG	Long	FE92		yyyy zzzz		Get long integer value of register A
READFLOAT	Float	FE93		yyyy zzzz		Get floating point value of register A
LINCA	Long	FE94				A = A + 1
LINCB	Long	FE95				B = B + 1
LDECA	Long	FE96				A = A - 1
LDECB	Long	FE97				B = B - 1
LAND	Long	FE98				A = A AND B
LOR	Long	FE99				A = A OR B
LXOR	Long	FE9A				A = A XOR B
LNOT	Long	FE9B				A = NOT A
LTST	Long	FE9C	ss			Get the status of A AND B
LSHIFT	Long	FE9D				A = A shifted by B bit positions
LWRITEA	Long	FEAx	yyyy zzzz			Write register and select A
LWRITEB	Long	FEbX	yyyy zzzz		x	Write register and select B
LREAD	Long	FECx		yyyy zzzz		Read register
LUDIV	Long	FEDx			x	Select B register, A = A / B (unsigned) Remainder stored in register 0
POWER	Float	FEE0				A = A raised to the power of B
ROOT	Float	FEE1				A = the Bth root of A

MIN (FMIN)	Float	FEE2				A = minimum of A and B
MAX (FMAX)	Float	FEE3				A = maximum of A and B
FRACTION	Float	FEE4			0	Load Register 0 with the fractional part of A
ASIN	Float	FEE5				A = asin(A) radians
ACOS	Float	FEE6				A = acos(A) radians
ATAN	Float	FEE7				A = atan(A) radians
ATAN2	Float	FEE8				A = atan(A/B)
LCOMPARE	Long	FEE9		ss		Compare A and B (signed long integer)
LUCOMPARE	Long	FEEA		ss		Compare A and B (unsigned long integer)
LSTATUS	Long	FEEB		ss		Get long status of A
LNEGATE	Long	FEEC				A = -A
LABS	Long	FEE D				A =  A
LEFT		FEEE				Left parenthesis
RIGHT		FE EF			0	Right parenthesis
LOADZERO	Float	FEF0			0	Load Register 0 with Zero
LOADONE	Float	FEF1			0	Load Register 0 with 1.0
LOADE	Float	FEF2			0	Load Register 0 with e
LOADPI	Float	FEF3			0	Load Register 0 with pi
LONGBYTE	Long	FEF4	bb		0	Write signed byte to register 0 Convert to long
LONGUBYTE	Long	FEF5	bb		0	Write unsigned byte to register 0 Convert to long
LONGWORD	Long	FEF6	www w		0	Write signed word to register 0 Convert to long
LONGUWORD	Long	FEF7	www w		0	Write unsigned word to register 0 Convert to long
IEEEMODE		FEF8				Set IEEE mode (default)
PICMODE		FEF9				Set PIC mode
CHECKSUM		FEFA			0	Calculate checksum for uM-FPU code
BREAK		FEFB				Debug breakpoint
TRACEOFF		FEFC				Turn debug trace off
TRACEON		FEFD				Turn debug trace on
TRACESTR		FEFE	aa ... 00			Send debug string to trace buffer
VERSION		FEFF				Copy version string to string buffer

**Notes:**

Data Type	data type required by opcode
Opcode	hexadecimal opcode value
Arguments	additional data required by opcode
Returns	data returned by opcode
B Reg	value of B register after opcode executes
x	register number (0-15)
n	function number (0-63)
yyyy	most significant 16 bits of 32-bit value
zzzz	least significant 16 bits of 32-bit value
ss	status byte
bb	8-bit value
www w	16-bit value
aa ... 00	zero terminated ASCII string

## Appendix B

### Floating Point Numbers

Floating point numbers can store both very large and very small values by “floating” the window of precision to fit the scale of the number. Fixed point numbers can’t handle very large or very small numbers and are prone to loss of precision when numbers are divided. The representation of floating point numbers used by the uM-FPU is defined by the IEEE 754 standard.

The range of numbers that can be handled by the uM-FPU is approximately  $\pm 10^{38.53}$ .

#### IEEE 754 32-bit Floating Point Representation

IEEE floating point numbers have three components: the sign, the exponent, and the mantissa. The sign indicates whether the number is positive or negative. The exponent has an implied base of two. The mantissa is composed of the fraction.

The 32-bit IEEE 754 representation is as follows:

#### Sign Bit (S)

The sign bit is 0 for a positive number and 1 for a negative number.

#### Exponent

The exponent field is an 8-bit field that stores the value of the exponent with a bias of 127 that allows it to represent both positive and negative exponents. For example, if the exponent field is 128, it represents an exponent of one ( $128 - 127 = 1$ ). An exponent field of all zeroes is used for denormalized numbers and an exponent field of all ones is used for the special numbers +infinity, -infinity and Not-a-Number (described below).

#### Mantissa

The mantissa is a 23-bit field that stores the precision bits of the number. For normalized numbers there is an implied leading bit equal to one.

#### Special Values

##### Zero

A zero value is represented by an exponent of zero and a mantissa of zero. Note that +0 and -0 are distinct values although they compare as equal.

**Denormalized**

If an exponent is all zeros, but the mantissa is non-zero the value is a denormalized number. Denormalized numbers are used to represent very small numbers and provide for an extended range and a graceful transition towards zero on underflows. Note: The uM-FPU does not support operations using denormalized numbers.

**Infinity**

The values +infinity and -infinity are denoted with an exponent of all ones and a fraction of all zeroes. The sign bit distinguishes between +infinity and -infinity. This allows operations to continue past an overflow. A nonzero number divided by zero will result in an infinity value.

**Not A Number (NaN)**

The value NaN is used to represent a value that does not represent a real number. An operation such as zero divided by zero will result in a value of NaN. The NaN value will flow through any mathematical operation. Note: The uM-FPU initializes all of its registers to NaN at reset, therefore any operation that uses a register that has not been previously set with a value will produce a result of NaN.

Some examples of IEEE 754 32-bit floating point values displayed as BASIC Stamp data constants are as follows:

```
